MELTDOWN: READING FORBIDDEN DATA

Meltdown basically works like this:

- READ secret from forbidden address
 - ¹ Check that program may read from address
 - Store the read value in register
- Stash away secret
 - Magic
- Retrieve secret (later)

μOPs: 1 2 1

MELTDOWN: READING FORBIDDEN DATA

μOPs ordered by instruction

- ¹ Check access
- Read into register
- 1 Magic

μOPs ordered by execution

- Read into register
- 1 Magic
- 1 Check access

The re-ordering on the right happens, when the "forbidden data" is already cached (because cache access is so fast).
